Ten days of a claim that was true and not yet reachable

Prepared for Marvin Percival, DUNIN7 · Version 5

Version 5, 13 November 2026. Version 1 was written on 10 November. Three things in it are no longer true, and they are marked in the page rather than edited away, because a document that hides its own revisions is the failure it describes.

WHAT CHANGED IN VERSION 5

The title. Version 4 said five weeks. The client's first message was on 3 November at 12:08 and the post went up on 13 November, so the review ran ten days, and he was right to ask for it. The same sentence in the post is corrected the same day. Nothing else in the page is touched, and version 4 stays exactly as he cleared it rather than being edited in place, because a document that hides its own revisions is the failure this page describes.

THE SITUATION, IN THREE SENTENCES

An open protocol project was preparing to describe its anchoring and verification story as complete. The author had built the segment code, the serialiser and the test vectors, and could demonstrate a byte match between producer and verifier on his own machine. Two things stood between that demonstration and the claim: whether a holder could reach the code path, and whether anything had ever been anchored on the network that a walk could read.

WHAT WAS REVIEWED

The producer and verifier as published at the revision the author pinned, the conformance packet, the vector files, and the specification text beside them. Every claim in the register was checked against one of those four surfaces and cited to a file and a line, because a review that cannot be re-run from its own citations is an opinion.

WHAT THE REGISTER FOUND

Four numbered entries in register version 7, W-01, W-02, W-03 and W-04, with W-01 carrying the sub-findings that the walk, the declared position and the anchoring each failed. One of them was load-bearing.

The producer serialised every batch header through the route that carries no segments, and both the batch accumulator and the Tier-2 aggregator used it. The full segments serialiser existed and was tested. On the surface the author tested, producer and verifier agreed byte for byte.

What the review added was a reachability question rather than a truth question. The segment path was real, and no outside client could invoke it: every lane an outside client could register bound to the aggregate. The proof was correct and the capability was not yet a capability. That distinction moved the finding from "the code is wrong" to "the claim is ahead of the surface", which is the finding the author accepted and reopened against his own test.

WHAT WAS WRONG FIRST, AND WAS CORRECTED

My register opened with a comparison that counted a test file's vectors as evidence of coverage. The author showed it counted a command he had not run, and the sentence was withdrawn rather than softened. A second claim, that a specific subsystem was closed, lost its heading and became a registered item instead. A third correction was mine alone: two commits were named without saying which was which.

Three corrections, two of them raised by the author and one found by re-reading my own text. The register carries a revision history for exactly this reason: a reviewer who reports only the corrections he was forced into is not keeping a record. Version 7's own header records a separate set, three editorial fixes applied in that version, the label, a stale count and the explanation of two counts. The two threes are not the same three, which is exactly the sort of sentence that has to be written down rather than remembered.

WHAT HAS CHANGED IN THE PROJECT SINCE

The project closed every item on the register in code or in text, which is the rarer half. One exception, W-04: it is closed in the text, and his record does not show a re-run of my probe against the rule that now states the mapping. So it is closed in the specification and not yet confirmed against my test, and that distinction is his, stated in his record before I asked for it. The verifier specification has moved from v0.10 to v0.14. The last three revisions each name the finding they answer, v0.12 answering A11 and A12 and the two after it naming the corrections raised in review. The earlier revisions name the section items they change rather than a finding, which is the smaller claim and the one that holds. A correction raised in the last exchange, that one amendment sentence still described the segments serialiser as unbuilt after it had been built, is closed in both places: Batch Anchoring Amendment v0.26 corrects the sentence, keeps the old wording visible as superseded, and points at the verifier rule; the specification now points at v0.26 instead of promising a revision that already exists.

THE ABSENCE THAT STOPPED BEING AN ABSENCE

Version 1 of this page ended with the one thing review could not establish: whether a non-zero segment range had ever been anchored on the public network, since no transaction identifier existed for one, and the absence of a record is not a record of absence.

That question was answered inside two days, by the project rather than by the review. On 10 November a header carrying a non-zero segment range was anchored through a client lane, and on 12 November a Tier-2 aggregate carrying such a header was anchored as well. Three anchors now sit on Kaspa mainnet, at 12:20:15 and 15:17:42 UTC on 10 November and 16:28:25 UTC on 12 November, and each payload is the anchored value and nothing else.

The second transaction spends the first one's output. The third does not: its input is an earlier transaction, and all three pay one address, which is consistent and is not lineage. The join of the third is inside the client header within the aggregate leaf, and that is not in the payload. So a holder with a browser can check each anchor and its block time, and the extent from sequence 0 to 8 is checked with the proof bundle.

This is the outcome the page argued for. The claim was not withdrawn; it was made reachable, and the record that proves it now exists rather than being promised.

WHAT IS STILL NOT ESTABLISHED

The mapping that closes W-04 is stated in the specification, and his record does not show a re-run of my probe against it. That is why the register's closure is a textual one: the rule exists, and the test of the rule is outstanding in the record rather than settled by it.

The live Tier-2 aggregate has one leaf, so the path from the client header to the aggregate root is empty on chain. A path with sibling hashes is covered by vectors and by the verifier's own tests, not yet by an anchor.

The producer takes the sequence number and the previous transaction hash from the request. It does not read them out of the record body, and neither does the verifier. The extent proves what was committed and in what order. It does not prove that the numbers match anything inside the records, and the specification says so.

The verifier's own test suite passes in full, 66 of 66, and that figure is not the conformance vector count. The specification's table of vector families totals 91 across seven families, and its own note records that the suite it describes runs 121 vectors in nine families at wire 4.3. A conformance claim has to name the suite version it was run against, and both numbers are in the text for anyone who wants to check which one is being used.

THE ARTEFACT

The register, revision seven, 34,757 bytes, SHA-256 beginning b9af6973, delivered to the author with a v6-to-v7 patch that applies cleanly and a negative control showing an already-patched tree refusing every hunk. The author holds the earlier revision and its hash, which is why version six was frozen rather than edited.

WHAT THIS IS WORTH TO A READER

Not a protocol review. A demonstration that the sentence a team is most confident about is often the one never tested from the position of the person the sentence is meant to convince.

NAMING, AND WHAT IT COSTS

He accepted the point that naming him does not protect anonymity: his name plus his published work makes the project findable by anyone who wants to find it, so a removal list stops doing its real work at the moment the name goes in. He chose to be named anyway, which is his call to make and not mine.

The section on where I was wrong first stays in, at his instruction and for the obvious reason.
